

Yes — what you're describing does work, but there are a couple of important details about how the display/output happens.

✅ Short answer

Proxmox VE can run Arch Linux with a GUI inside a VM.

You can install Firefox or Google Chrome inside that VM.

BUT the way you see the browser output depends on your setup.

💻 How the display actually works

1. Default method (no GPU passthrough)

Proxmox gives you a virtual display (VNC/SPICE).

You open the VM console from your browser.

You'll see Arch's desktop + Firefox running there.

👉 This works, but:

Graphics are software-rendered

Performance is okay for basic browsing, not great for video/3D

2. Better method (Remote desktop)

Instead of using Proxmox console:

Install a desktop (KDE, GNOME, XFCE) in Arch

Run:

XRDP or

VNC

Then:

Connect from your real PC using Remote Desktop

You'll see Firefox/Chrome like a normal computer

👉 This is much smoother than Proxmox console.

3. Best performance (GPU passthrough 🚀)

If you want near-native browser performance:

Pass a real GPU into the VM (PCI passthrough)

Arch uses the GPU directly

Firefox/Chrome get hardware acceleration

👉 Result:

Smooth video playback

Real desktop-like experience

🧠 Important clarification

You asked:

“can we get the chrome output or firefox output”

Yes — but:

The browser runs inside the VM

You are just viewing it remotely

It's not "streamed into your host browser tab" automatically (unless you build something custom like a web VNC gateway).

 Alternative (lighter approach)

If your goal is just to run a browser remotely:

Use a container + headless browser

Or tools like:

noVNC

Apache Guacamole

These let you open the VM desktop inside your real browser tab.

 Summary

✓ Yes, fully possible

✓ Arch Linux GUI works fine in Proxmox

✓ Firefox/Chrome will run normally

How you see it:

Basic → Proxmox console

Better → Remote desktop

Best → GPU passthrough

If you want, I can show you a step-by-step setup (Arch + GUI + Firefox on Proxmox) or help you choose the best method based on your hardware.

OK that's good I have a few question about Proxmox Can we install Proxmox from single computer to another computer think like you have you are admin and you are a section to manage your computer so you have to go install one by one proximo or can you install one computer to all computers procmok setups and the on top of that inside of that can be run browser with a display or GUI output. Simply I mean can we manage install Proxmox on one computer another computer If and can we authorize only who do that that means only admin can do that not another user can't edit others proxmoor setups

Yes — what you're describing is basically centralized deployment + controlled access, and Proxmox VE can support parts of it, but not everything out-of-the-box. Let me break it down clearly.

 1. Can you install Proxmox on many computers from one computer?

 Directly from Proxmox itself?

No — Proxmox is not a mass installer.

It does NOT natively:

Push installs to other machines

Automatically deploy itself to multiple PCs

 How people actually do this (real-world way)

You use external tools like:

PXE boot

Clonezilla

Ansible

Example workflow:

Set up a PXE server

All target machines boot from network

Automatically install Proxmox on each

👉 This is how admins deploy to 10, 50, 100+ machines

🧠 2. Once installed — can you manage all Proxmox servers from one place?

✅ YES (this is where Proxmox shines)

You create a cluster

Multiple Proxmox nodes join together

Managed from one web interface

👉 You can:

Create VMs on any node

Start/stop VMs remotely

Monitor all systems

🔒 3. Can only admins control it (and block other users)?

✅ YES — very strong control system

Proxmox has role-based access control (RBAC):

You can define:

Who can login

What they can do

Which machines they can touch

Example roles:

Admin → full control

User → only view or start their own VM

No access → cannot even see other nodes

👉 You can also integrate with:

LDAP

Active Directory

So only authorized people can manage systems.

🌐 4. Can users run a browser (GUI) inside Proxmox VMs?

✅ YES (what you asked earlier)

Inside each VM (like Arch Linux):

Install GUI (KDE/GNOME)

Run Firefox or Google Chrome

Users access it via:

Browser console (basic)

Remote desktop (better)

✚ Putting it all together (your idea)

What you're imagining is like:

“One admin computer controls everything, installs everything, and users only access what they're allowed”

✓ Possible architecture:

Deployment

Use PXE / Clonezilla to install Proxmox on many machines

Management

Create a Proxmox cluster

Control all nodes from one web UI

Security

Use RBAC + LDAP/AD

Only admins can modify systems

Usage

Users log in

Access their VM

Run browser inside VM

⚠ Important reality check

Proxmox alone is:

✓ A virtualization manager

✗ NOT a full “enterprise device management system”

If you want something like:

Push OS installs

Manage users/devices centrally

Lock down computers

You usually combine Proxmox with:

Foreman

MAAS

Or Microsoft tools like Microsoft Endpoint Manager

✓ Final answer (simple)

✓ You cannot install Proxmox on other computers directly from Proxmox

✓ But you can automate installation using PXE or cloning tools

- ✓ After installation, you can manage all machines from one place (cluster)
- ✓ You can restrict access so only admins control everything
- ✓ Users can run GUI apps (like browsers) inside VMs

If you want, I can design a simple home lab or company setup diagram showing exactly how to build this system step by step.

Or can we create an applications like for window Exe file Once config dole arts and browser setups and create a one single execution file and install the all essentials things

Short answer: yes, you can bundle and automate a lot into a single installer, but not everything (especially full OS installs like Proxmox). Let me break it down clearly so you don't hit a wall later.

 What you're trying to do

You want something like:

“Run one .exe → installs apps + config + browser + setup everything automatically”

That's totally possible for Windows apps, but not for installing an entire OS like Proxmox.

 1. Can you make a single EXE installer for apps?

✓ YES (very common)

You can create a custom installer using tools like:

Inno Setup

NSIS

WiX Toolset

💡 What your EXE can do:

When user runs it:

- ✓ Install **Google Chrome or Firefox
- ✓ Install other software
- ✓ Copy config files
- ✓ Set registry settings
- ✓ Create shortcuts
- ✓ Even run scripts (PowerShell, batch)

👉 Basically: full environment setup in one click

⚙️ 2. Even easier: use package managers

Instead of building everything manually:

Chocolatey

Winget

You can make a script like:

```
winget install Google.Chrome
```

```
winget install Mozilla.Firefox
```

Then bundle that into an EXE.

✖ 3. What about Proxmox?

✖ You CANNOT:

```
Install **Proxmox VE using a Windows .exe
```

```
Run it like a normal application
```

👉 Because:

```
Proxmox is a full operating system (based on Debian Linux)
```

```
It must be installed via:
```

```
ISO
```

```
USB boot
```

```
Network boot (PXE)
```

🔄 4. But you CAN automate Proxmox setup

```
After installation, you can automate config using:
```

```
Shell scripts
```

```
Ansible
```

Example:

Create users

Configure storage

Create VMs

Install templates

 5. Best real-world approach (what pros do)

◆ Step 1 — OS deployment

Use PXE / cloning (not EXE)

◆ Step 2 — Auto configuration

Scripts or Ansible

◆ Step 3 — App installer (your EXE idea)

For Windows VMs or user PCs

 Think of it like layers

Layer Tool

OS install ISO / PXE

Server setup Ansible

Apps install EXE / Winget

✅ Final answer

✓ You can create a single EXE to install apps + browser + configs

✓ This works great for Windows environments

✗ You cannot install Proxmox using an EXE

✓ But you can automate Proxmox setup after installation

 Simple analogy

Proxmox = installing the entire building

Your EXE = arranging furniture inside rooms

If you want, I can:

Show you how to build a real EXE installer step-by-step

Or create a script that installs Chrome + Firefox + configs automatically in one click

Or design a full enterprise-style deployment system based on your idea
